MEMORANDUM

ON THE

AGE TABLES AND RATES OF MORTALITY

OF THE

INDIAN CENSUS OF 1901.

BY

G. F. HARDY.

CALCUTTA:

OFFICE OF THE SUPERINTENDENT, GOVERNMENT PRINTING, INDIA
1905.

MEMORANDUM

ON THE

AGE TABLES AND RATES OF MORTALITY

OF THE

INDIAN CENSUS OF 1901.

1. In my Report upon the ages of the people of India, as enumerated in the Census of 1881, I have pointed out and discussed the special difficulties attending any attempt to employ the results of such periodical enumerations for the investigation of the rates of mortality or the average duration of life prevailing in the various provinces. These difficulties it will be necessary to refer to again in some detail, but it will be sufficient to state here that they arise mainly from the inaccuracy of the ages as returned, to the serious disturbances in the numbers returned for certain age groups due to the marked decrease of births during famines, to the incompleteness of the registration returns and in a smaller degree to some uncertainty as to the completeness of successive enumerations, and hence as to the true rate of increase of the population between successive censuses. Further, the large fluctuations in the death-rates in India (in Bombay, for example, during the 10 years 1891—1901 the mortality rates have been about 50 per cent. higher than in the preceding 10 years) add to the difficulty of the problem, as it is impossible to base a life table of any practical value upon the abnormal mortality rates of a single period.

2. The 1881 census immediately succeeded a period of famine which was nearly general throughout India, and in some provinces so severe as to produce a very considerable diminution in the population since the previous enumeration in 1871-72. As is now well known the effect of such a famine immediately preceding an enumeration is seriously to disturb the normal age-distribution, especially (as a result of the much-diminished birth-rate prevailing during the period of famine) in the relatively small number of children found between the ages of 0 and 5 at the census. Hence the age returns in the 1881 census could not be looked upon as representing the average age distribution of the population. In the case, however, of those provinces most affected by the 1877 famine, the conditions at the previous enumeration in 1871 and 1872 were of an opposite character, the census following a prosperous period with high birth-rates, and it was possible by comparing the relative age distribution at these two epochs to arrive at a fair estimate of the normal age distribution. This was accordingly made the main object of my report upon that occasion, and the tables appended thereto purported to give an estimate both of the normal age distribution of the population and (as deduced therefrom, in conjunction with the estimated average rates of increase) of the rates of mortality and expectations of life at each age, and the approximate birth and death-rates for the principal provinces when averaged over a long series of years.

3. The memorandum in connection with the 1891 enumeration, on the other hand, dealt with a period generally free from famine, provinces which had shown but a small increase or even a decrease in the previous decennium, then showing a very considerable advance in population. It was therefore considered desirable to deal with the rates of mortality of the inter-census period and thus obtain a measure of the mortality and of the average birth

and death-rates prevailing among the natives of India when freed from the disturbing effect of periodical famines.

As a result, the tables of mortality given in the 1891 report showed on the whole a considerably larger expectation of life at all ages than those appended to the earlier report.

4. The census of 1891 was similar in its conditions to that of 20 years earlier. It was preceded in 1896 and 1897 by a severe famine affecting large areas of the country and producing disturbances in the age statistics similar to those observed in 1881, while, in the case of the Bombay Presidency especially, the effects of the famine have been aggravated by a severe visitation of plague, the combined result being seen in a diminution of the population, by about 2 per cent., since 1891. In these circumstances, while an enquiry into the age returns at the last enumeration may usefully deal, amongst other questions, with the rates of mortality found to have prevailed during the past 10 years, as compared with those of the preceding decennium, it would be useless to construct mortality tables based upon what is a quite abnormal period, and I have therefore, as in 1881, attempted to produce average mortality tables for each of the principal provinces in the light of the fresh data obtained since that date.

5. The data available for the enquiry on the present occasion do not differ in their nature from those available in 1891.

They are briefly as follows :—

- (1) The census tables for age and sex for each province, giving the numbers returned for the usual age groups 0, 1, 2, 3, 4, 5—9, 10—14, etc., 60 and upwards (Imperial Table) VII.
- (2) Additional schedules showing the numbers returned at each age out of 100,000 specimen cases for each sex, taken at random.
- (3) The proclaimed class statistics, described in my previous memoranda, giving rates of mortality for the earlier ages up to age 12.
- (4) Birth-place returns (Imperial Table XIII), showing the extent of migration.

6. Ordinarily these would be supplemented by birth and death registration returns; but while there is no doubt a gradual improvement in registration in most of the provinces, these returns are still too defective to form the basis of any satisfactory estimate of the rates of mortality prevailing at various ages throughout life, unless in quite exceptional districts; nor do I think they can even be considered with safety to indicate the relative mortality for different periods of life, as, apart from the errors in statements of age, which are no doubt at least as great as in the census returns, it is quite possible that registration in childhood and infancy is less complete than in adult life. I shall, however, return to this subject later and endeavour to give some estimate of the extent to which registration is defective in the principal provinces.

TABLE I.

Mortality experience of the Proclaimed Clans (North-West Provinces).

1876—1900.

MALES.

NUMBER OF DEATHS REGISTERED OUT OF 10,000 "AT RISK" AT EACH AGE.					MORTALITY TABLE. NUMBERS LIVING OUT OF 100,000 MALE CHILDREN BORN.				
Age.	1876-81 (6 years).	1882-90 omitting 1887 and 1889 (6 years).	1876-90 (15 years).	1891-1900 (10 years).	Age.	As deduced from column (4).	Graduated numbers.	Age x.	Living at age x (1x).
(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)	(10)
0-1	2,333	2,301	2,317	2,155	At birth ...	100,000	100,000	0	100,000
1-2	1,333	1,262	1,297	1,143	Aged 0-1	76,830	76,792	1	70,213
2-3	786	959	873	682	„ 1-2	66,865	66,662	2	63,618
3-4	506	591	549	357	„ 2-3	61,028	61,325	3	59,813
4-5	384	449	417	288	„ 3-4	57,678	57,753	4	56,368
5-6	291	333	312	188	„ 4-5	55,273	55,270	5	54,285
6-7	245	290	267	...	„ 5-6	53,549	53,495	6	52,758
7-8	181	211	196	...	„ 6-7	52,119	52,151	7	51,591
8-9	150	167	159	...	„ 7-8	51,098	51,109	8	50,658
9-10	132	173	153	...	„ 8-9	50,295	50,257	9	49,877
10-11	120	133	127	...	„ 9-10	49,516	49,529	10	49,194
11-12	137	97	117	...	„ 10-11	48,887	48,881	11	48,576
					„ 11-12	48,315	48,286	12	48,001

NOTE.—The figures in column (8) representing the graduated numbers living between ages x and $x+1$ out of 100,000 births are given by the formula $f_0^x \frac{dx}{dx} = 53,675 x - 216 x^2 + 57,135 (65)x + 2,300 \log_{10} (20x+1)$ which, as will be seen, follows fairly closely the ungraduated curve, and from which may be at once deduced the expression for the numbers living at exact age x out of 100,000 births, as given in column (10), *i.e.*, $x-1 = 53,675 - 493 x + 23,810 (65)x + \frac{31,715}{20x+1}$.

9. As regards the rates of mortality of adult life, the only data which have any claim to completeness are the age returns of successive enumerations. As is evident, assuming these age returns were trustworthy, and that the average rate of increase per annum of the population was accurately known, together with the extent and manner in which it was affected by migration, we should be in possession of the materials for determining the rates of mortality at the various ages throughout life. Here, however, we encounter the difficulty which always arises in census returns, and very specially so in those of India, *i.e.*, the inaccuracy of the ages returned.

10. The errors in the age returns are of two kinds. The first may be termed accidental errors or irregularities, due to the tendency of persons to return their ages as multiples of 10 and to a lesser extent as multiples of 5, and not necessarily involving under or over-statement of age. The second class may be termed systematic errors, due to the tendency at certain periods of life to under-estimate, and at other periods to over-estimate, the true ages. The effect of both classes of error in combination is to produce very great irregularities in the progression of the numbers returned at successive quinquennial age groups, irregularities which are still further increased by a real defect in the numbers living at certain of these age groups, representing the survivors of the persons born during past famine periods when the birth-rate was below the average. To overcome these various sources of error and to deduce from the recorded numbers at the various age groups an approximation to the true numbers living at these ages is by no means easy.

11. Dealing first with the disturbance caused by the excess of persons returned at the decennial and, in less degree, at the intervening quinquennial ages, the method employed in 1881 was based upon the fact that in the 1881 census the ages *last birthday* were recorded and in 1871-72 the ages *next birthday*, the result being that the excessive numbers returned at the quinquennial ages fell into different groups (the large number returned, for example, as aged 30 next birthday in 1871-72 being included in the group 25-30, the corresponding number returned as 30 last birthday in 1881 being included in the group 30-35). Thus, by taking a mean of the numbers returned at these two censuses in the successive groups, the effect of the heaping up at the quinquennial ages was practically eliminated.

12. In 1891 it was considered desirable to obtain some evidence as to the actual numbers returned in the enumeration at each individual age, and as it was impracticable to tabulate this information for the entire population, returns were made in this form, deduced from 100,000 specimen cases, taken at random, for each sex, in each of the principal provinces. Assuming that these specimen cases were representative of the average population of the province, it was possible to deduce therefrom, with a fair degree of approximation, the actual numbers returned at each age for these provinces, upon the assumption that the relative distribution in any given quinquennial group would be similar in the total for the entire province to that shown in the same group in the specimen schedule.

13. On the present occasion similar specimen returns have been obtained, and a selection from these is reproduced in Table A. A reference to this table will show at once the mean features of the age returns, and in particular the relatively enormous numbers returned at such ages as 25, 30, 40, 50, etc.

14. The 1901 specimen schedules are more varied in character than those of 1891, but in one or two instances appear to be less representative. In the case of the schedule for Madras, for example, the numbers at successive ages during the earlier years of life run with great regularity, and, indeed, throughout life they present a marked contrast to the specimen schedule for the same province in 1891. The reason for this is fully explained by the paragraph in Mr. Francis' report (Volume I, page 50), from which it would appear that the schedule has reference "to families in Madras City following certain selected occupations, such as clerks, vakils, superior tradesmen, etc., the assumption being that persons of this amount of education would be more accurate in their returns of age than the common herd." As a result, while this return is of value on account of certain special features which it possesses, more particularly with reference to the age distribution during the first 15 years of life, it cannot be taken as typical of the general population of the province, and cannot be used to adjust the population returns for the excess numbers returned at the quinquennial ages. For this purpose, therefore, the specimen returns from Madras, compiled in 1891, have been employed. In the case of some other provinces, e.g., Central Provinces, specimen schedules have been prepared showing the age distribution in famine and non-famine districts, respectively, which are of considerable value as indicating the effect of the famine upon the relative numbers living at various periods of life, but cannot be taken as representing the average of the province as a whole.

In Bengal and the North-West Provinces separate schedules were prepared for Hindus and Mohamedans, and, in order to produce specimens representative of the province as a whole, these have been combined in proportion to the relative numbers of these religions, the minor religions being classed for this purpose with Hindus. Thus, in Bengal, the specimen schedule reproduced in Table A is obtained from the original schedules for Hindus and Mohamedans, giving them relative weights of 7 and 4, respectively, the proportions for the North-West Provinces being 7 and 1.

15. The object of these specimen schedules was, primarily, as stated above, to obtain a measure of the extent of the disturbance in the age statistics caused by the heaping up of the numbers at the quinquennial ages, and, in the second place, to obtain information as to the age distribution above age 60. For this purpose the number returned at each age group, commencing with the group 5 to 9, having been first reduced to correspond to a total population of 100,000 for each sex, was distributed over each of the five years in proportion to the

numbers at each age of the corresponding group in the specimen schedule. The resulting figures are given in Table B, and were arrived at as shown in the following detailed example. The number of males returned in Bengal as between 50 and 55 corresponded to 3,916 on the basis of a total population of 100,000; the numbers in the specimen schedule (Hindus and Mohamedans combined) for this group of ages is 3,795—see Table A—distributed as in column (2) in the following table. Hence by raising the numbers in column (2) in the ratio of 3,916, to 3,793 the figures shown in the final column and reproduced in Table B are obtained:—

Province of Bengal.

Age group 50—55 (male).

Age. last birthday.	(1)	Number in specimen schedule (Table A).	(2)	Census number distributed in same proportion.	3,916
50	.	2,821	2,821	2,911	2,911
51	.	194	194	200	200
52	.	513	513	530	530
53	.	101	101	104	104
54	.	166	166	171	171
		Total of group	3,795		3,916

In this way the whole of the figures in Table B were obtained from age 5 upwards.

16. To obtain the figures in Table C, the same process was adopted as in my memorandum on the 1891 census, which may be illustrated from the same section of the Bengal Table as follows:—

Bengal Males number returned at age 50 (Table B)	.	.	.	2,911
Mean of numbers, ages 49 and 51	.	.	.	193
Difference	.	.	.	2,718

Of this last number, it was assumed that one-half (1,359) should be in the group 45—50, and the other half in the group 50—55, and so on, for each quinquennial age throughout the table, the figures in Table C resulting. Hence Table C may be taken to represent the age distribution of the population as censused when freed from disturbances due to purely accidental causes, such as arrangements of the age groups quinquennially and the recording of ages as at last birthday, but it contains what I have termed the systematic or inherent errors due to any general tendency to over or under-estimate the ages for various periods of life.

16 A. The method of dealing with this last-mentioned class of errors has now to be considered. Much has been written on this subject by some of the authors of the provincial reports, but it appears to be extremely difficult to establish any general method by which errors of this nature can be detected and allowed for. Were the tendency a purely local one, affecting only an isolated age group, e.g., the transference of a number of lives from a particular age group to the group adjoining, it would so affect the progression of the numbers as to be easily detected, and the extent of correction required might possibly be estimated with some fair approach accuracy. It is quite possible, however, for a general tendency to under-or over-estimate the true ages to exist, without producing any evidently abnormal progression in the recorded number.

17. There are two possible tests which may be applied with a view to detecting any systematic error of this nature, though neither of them are absolutely satisfactory. The first of these is an examination of the relation borne by the numbers returned in any age group with the numbers returned for the group 10 years younger at the previous census, of whom they are the survivors. Assuming both numbers to be correctly returned, the relation between the two would give a measure of the probability of surviving the intervening period of 10 years, and, by inference, of the average rate of mortality of the group for the period in question. As experience goes to show that there are

certain general laws applying to the relative rates of mortality at the various periods of life, an examination of the ratios above referred to of various groups should result in throwing some light upon systematic age misstatements we are now dealing with. This test is in principle that adopted in adjusting the age tables, as it practically amounts to drawing a smooth curve through the ungradiated figures, which shall at the same time adhere as closely as possible to the latter while avoiding any anomalous progression in the resulting mortality rates.

18. A second test that might seem to be promising is based upon the consideration which has already been referred to, that during any period of severe famine the birth-rate is so much lowered as to lead us to expect at any future census a marked depression in the age curve at these ages representing the survivors of those born during the famine period. It would then appear that if, for example, there is a marked tendency to under-estimate or over-estimate the ages at a particular period of life, any depression in the curve at this point of the kind we are now dealing with would be correspondingly shifted towards a younger or older group. On the other hand, assuming no such general tendency to either under- or over-estimate to prevail, then the depression might be expected to be found in its proper place in the table, although possibly somewhat overlaid and obscured by the general inaccuracy of the returns.

19. As an example, I may refer to the Madras returns for the three successive enumerations, 1881, 1891 and 1901. On examining the figures for the male population, given in Table C, where the numbers are assumed to have been freed as far as possible from the accidental errors due to excessive numbers returned at decennial and quinquennial ages, it will be seen that the numbers living under age 5 in 1881 are considerably below the average of this group, especially if allowance is made for the fact that in 1901 the numbers in this group were diminished by the effect of the recent famines in 1896 and 1900. The survivors of the children under 5 in 1881 are represented by the group 10 to 14 in 1891, which is again much below the average for this age-period. Finally, in the 1901 return it will be seen that the survivors now aged from 20 to 24 are represented by a group about 10 per cent. below the normal, while the adjacent groups 15 to 19 and (especially) 25 to 29 are also somewhat below the average, indicating probably that the gap caused by the depressed birth-rate prior to 1881 has been partly spread over the adjacent age groups as a result of inaccuracy in the age returns and that a portion of the male population aged 20 to 24 have given their ages from 15 to 19 and a somewhat larger number from 25 to 29.

20. The application of this test, however, to later age groups, by an attempt to trace the effects of former famines, such as those of 1854 or 1877, does not lead to any useful results. No doubt the increasing inaccuracy in statements of age beyond middle life has a tendency to obliterate depressions in the curve which might otherwise appear, while a further difficulty arises from the uncertainty as to the relative severity of earlier famines and the extent to which they may have affected the birth-rate for the period in which they occurred. There is also the great probability that the individuals born during a period of famine are from a better stock, socially and physically, than the average, so that the survivors after 50 or 60 years from the small but more select group may be nearly as numerous as would be the survivors from the larger number born under normal conditions.

21. A systematic examination of the numbers from this point of view would be a very complicated matter, and it is very doubtful whether it would throw any real light on the question. If there is any marked tendency at or beyond middle life either to under-state or over-state the ages, it is not probable that such a tendency can be readily established by an examination of the returns themselves, and it is therefore almost hopeless to correct them for any possible errors of this nature.

22. A point of considerable interest discussed by Mr. Gait with reference to the Bengal tables, but applying to the whole of the Indian figures, is the relatively small number of children returned as aged 1 to 2. In most of the provinces, with the important exception of Bihar and the Central Provinces,

the numbers returned at this age are very much below those returned at the adjacent ages 0 to 1 and 2 to 3. In Bombay and Bengal, for example, the numbers returned at age 1 are less than one-half those returned as between 0 and 1, while in Madras, Bengal and the North-West Provinces they are very little more than one-half the latter numbers. The same tendency to an equally marked extent is shown by the 1891 figures, although in 1881 this feature was by no means so prominent, except in the Punjab, especially if we allow for the fact that in 1879 and 1880 the birth-rate had not completely recovered from the severe effects of the famine. Mr. Gait's explanation of this feature of the returns (see Bengal Census, Volume I, 209) may be conveniently summarised in the following tabular form:—

Ages as given in enumeration.	Persons probably enumerated at these ages.
0	Those between 0 and 1— <i>minus</i> some weaned infants under 1; <i>plus</i> some unweaned infants over 1.
1	Those between 1 and 1½— <i>plus</i> some weaned infants under 1; <i>minus</i> some unweaned infants over 1; <i>minus</i> some between 1 and 1½ who are prematurely called 3 (a favourite number).
2	Those between 1½ and 2½— <i>minus</i> some prematurely called 3 (see above).
3	Those between 2½ and 3— <i>plus</i> some between 1 and 2½ and a few between 4 and 5 erroneously called 3.
4	Those between 3 and 4— <i>minus</i> some erroneously called 3 and some called 5 (also a favourite number).
5	Those between 4 and 5— <i>plus</i> some from adjacent ages, etc.
x	Those aged x next birthday.

23. Here again there are no means of definitely determining from the figures themselves the extent to which these tendencies have prevailed. Allowing for the low birth-rate throughout India in 1900, the progression of the age figures in most of the provinces would appear to be fairly normal, if the assumption is made that one-half of those actually between ages 1 and 2 were returned at age 2, to 3, and that at subsequent ages, up to age 5, about 50 per cent. of the ages returned are ages next birthday instead of last birthday, but that the number returned as under age 10 is approximately correct when a due proportion of the excess numbers at age 10 is included in the group 5 to 9. On the principle of not making a greater adjustment than is obviously required by the figures themselves, I have therefore adopted this assumption.

CALCULATION AND GRADUATION OF AVERAGE AGE TABLES FOR PERIOD 1881 TO 1901.

24. Taking India generally, it has already been remarked that the periods 1881 to 1891 and 1891 to 1901 are of an opposite character, both the first and the last of the three censuses having succeeded periods of famine, heavy mortality and depressed birth-rate generally, while at the intermediate census an opposite condition of affairs prevailed. If we go back still further to the census of 1872, we have again a condition of things similar on the whole to that in 1891, the census having followed a period of general prosperity. The census of 1872, however, was far from complete, and the figures were probably less trustworthy than in subsequent enumerations. A fair estimate of the normal age distribution of the population will be obtained by taking an average of the last three censuses, but giving double weight to the figures in 1891, as it is a reasonable supposition that the average age distribution for the 20 years 1881 to 1901 will not differ greatly from the average, taking one period with another, over a long series of years. The resulting figures will represent a

mean between the age distribution in periods of prosperity and that in periods of scarcity, and will probably be very near to the figures that would be obtained as an average for the last 40 years, supposing that data for these were available. These figures are given in Table C for the principal provinces.

25. The numbers returned in the censuses 1881 and 1891 in quinquennial age groups having been corrected for the excessive numbers returned at quinquennial ages in the manner already described by the aid of the specimen schedules furnished in 1891, and a similar process having been applied to the 1901 figures, by the aid of the schedules provided on the present occasion, an average of these three returns, giving double weight to 1891, has been taken and the resulting figures given in the column headed "Mean, 1881—1901."

These are the figures which form the basis of the graduated age tables given in Table D, with the exceptions of Madras and North-West Provinces, in which cases the figures given in Table II as corrected for the effect of emigration have been substituted.

26. The process of graduation employed has been somewhat similar, though not identical, with that adopted in 1881.

It has been found rather more convenient to deal with the numbers representing the "population living above age x " than with the population as returned between given ages, and, as a first step, a preliminary graduation of the male tables for age 15 upwards was made by the use of the following formula, where N_x represents the numbers living out of a total male population of 100,000:—

$$\log N_x = K + ax + bx^3 + mc^x,$$

where the value of C was taken as $(10 \cdot 039)$ ($\log c = .039$), this value being indicated by the graduated population table for India constructed upon the basis of the 1881—1891 census figures, the value of the remaining four constants K , a , b and m being obtained from the numerical values of N_x when $x = 15, 45, 55$ and 65 , the values at ages 25 and 35 being unreliable.

27. The use of some such formula is rendered necessary by the fact that the age statistics are quite untrustworthy above age 65, and the figures for the latter periods of life can only be obtained upon the assumption that the progression of the rates of mortality is in India similar in character to that prevailing in other populations.

The character of the above function accords very closely with the nature of the normal population curve, and having four unknowns (when the value of C is assumed), it is sufficiently flexible. The graduations thus obtained were, however, adopted only for ages above 55, the graduated curve below that age being drawn to follow the census numbers as nearly as was consistent with the avoidance of abnormal progressions of the rates of mortality, while joining on smoothly to the values for ages 0 to 10 obtained by means of rates of mortality based on the Proclaimed Clans experience. In Bombay, the table deduced from the Proclaimed Clans experience was used unmodified, in Bengal the progression of the figures at the earlier ages, and in especial the proportion of the male population under age 15 indicated a rate considerably higher than that of the Proclaimed Clans table, and to obtain a satisfactory graduation of the figures it was necessary to assume an addition of 100 to the numbers dying between ages x and $x + 1$ from 0 to 10.

In Madras and the North-West Provinces these numbers were diminished by 10 per cent., and in Burma by 20 per cent., these changes also being necessary to reproduce approximately the population curve at the younger ages. The totals of the five large provinces, excluding Burma, have been taken as sufficiently representative of the whole of India, including as they do 80 per cent. of the entire population, and the tables for India have therefore, as in previous occasions, been obtained by taking an average of the five principal provinces, giving to each a weight corresponding to its population. This resulting curve is not such as would be expected to prevail at any one moment, but will afford a convenient standard of comparison to which the numbers at any special enumeration can be referred and by the aid of which the special characteristics of such enumeration will be more readily thrown into relief.

28. Special tables have been constructed for Burma, as there is good reason to suppose that the age returns are much more accurate in that province than

elsewhere in India, and a special interest attaches to these tables, as they show rates of mortality which are throughout much nearer to the European standard than is the case in any other province.

Migration Returns.

29. Taking India as a whole, immigration and emigration are not very important as affecting either the rate of increase of the population or the age distribution of the people. In certain provinces, however (such as Madras, North-West Provinces and Burma, among the larger areas), the movement of population is sufficiently important to take into account. This has been done on the same principle as that employed in 1891 by dealing with the population native to the province, whether living there or elsewhere in India. The only method available for determining the effect upon the age distribution of such emigration is that adopted in my last report, where a comparison is made of the age distribution in certain special provinces, such as Coorg, where the immigrants were relatively very numerous with that in India as a whole. From such comparison the relative proportion of immigrants for the various age groups were deduced, and suitable corrections applied to the enumerated populations in Madras and the North-West Provinces in the same manner as shown in detail in Tables V and VIII in my report on the 1891 census.

30. On the present occasion the same age distribution among the emigrants has been adopted (with some insignificant modifications), and it has been assumed that the excess of emigrants over immigrants per 100,000 of the population found in 1891 (*viz.*, 2,890 for Madras and 1,919 for the North-West Provinces) may be taken as representing the average for the 20 years 1881-1901. The following table will then show the extent to which the incorporation of the emigrant with the home population modifies the age distribution of the latter, the modified figures being used in lieu of those in Table C as the basis of the graduated age tables:—

TABLE II.

Correction of age tables for effect of Emigration (Madras and North-West Provinces).

Age.	MADRAS.				NORTH-WEST PROVINCES.			
	Mean population.	Emigrants.	Population, including emigrants.	Reduced to totals of 100,000.	Mean population.	Emigrants.	Population, including emigrants.	Reduced to totals of 100,000.
0-4	18,951	4	18,955	18,563	12,878	3	12,881	12,683
5-9	15,457	23	15,480	15,045	13,967	15	13,982	13,719
10-14	10,556	162	10,718	10,417	11,170	108	11,278	11,066
15-19	10,205	243	10,448	10,155	9,910	161	10,071	9,881
20-24	7,843	390	8,233	8,002	8,914	259	9,173	9,000
25-29	9,221	516	9,737	9,403	9,423	343	9,766	9,582
30-34	6,958	425	7,383	7,176	7,492	283	7,775	7,629
35-39	7,014	325	7,339	7,133	6,963	215	7,178	7,043
40-44	5,078	247	5,325	5,175	5,496	163	5,659	5,552
45-49	4,315	188	4,478	4,376	4,355	125	4,490	4,396
50-54	3,029	138	3,192	3,078	3,359	92	3,451	3,356
55-59	2,437	89	2,503	2,456	2,355	58	2,413	2,368
Over 60	3,936	140	4,090	3,961	3,718	94	3,912	3,740
Totals	100,000	2,890	102,890	100,000	100,000	1,919	101,919	100,000

31. In the case of Burma, where there is a large immigrant population, it has been considered that the difficulty thence arising can best be met by dealing

with the Buddhist population only, as this represents some 86 per cent. of the community and is presumably very little affected by immigration from outside the province.

Rates of Increase.

32. To deduce from the adjusted population tables the fundamental column of the mortality tables, representing the numbers surviving at each age from a fixed number of births, say, 100,000, it is necessary to determine the normal rates of increase for each of the various provinces. This problem was dealt with in 1881, and from an analysis of all the available data certain conclusions were arrived at as to the average rate of increase for the principal provinces prior to 1881, taking one period with another (see Census Report, 1881, Volume 1, pages 149—160).

33. In the case of Madras province (British districts), it was then estimated that the normal rate of increase in non-famine periods, as from 1856 to 1871, was 11·8 per mille per annum. Between the censuses of 1871 and 1881, an interval of $9\frac{1}{2}$ years, the population diminished (allowance being made for floating population unenumerated in 1871), on the average about 7·3 per mille per annum, owing to the severity of the 1877-78 famine. Combining these rates in due proportions and allowing 1 per mille per annum decrease as the result of emigration, a normal rate of increase of 6 per mille per annum for the period anterior to 1881 was arrived at.

34. The allowance of 1 per mille per annum for emigrants is in accordance with more recent data. It is shown in my memorandum on the 1891 census (see table on page 149) that about 1,400 male emigrants are required each five years, to maintain an emigrant population of 8,628 males, say, 3 $\frac{1}{4}$ per cent. per annum, and as the Madras emigrants (taking the 1891 figures to represent the average of the last 20 years) are about 2,900 out of a total native population of 100,000, this number would require about 100 or 1 per mille per annum to maintain it. The observed rate of increase in the male population of the Madras province (British districts) in the 10 years 1891—1891 was 14·5 per mille and in the 10 years 1891—1901, 6·7 per mille per annum, averaging for the 20 years 10·6 per mille per annum, which, making an addition of 1 per mille for emigration, gives a "natural" rate of increase since 1881 of 11·6 per mille. Combining these figures with the 6 per mille arrived at for the period 1856—1881, we should get an average "natural" rate of increase of about 8 per mille per annum. In the light of the subsequent history of the province, however, the famine of 1877-78 would appear to have been so abnormal in severity that I have no doubt the average rate of increase prior to 1881 was under-estimated, and that it should have approximated to the average rate deduced for those districts in the province less severely affected by the famine, *viz.*, 8 per mille. If this figure is adopted as the rate for 1856—1881 and combined with the observed rate since, we get an average rate which (making a fractional allowance for possibly improved enumeration) may be taken at 9 per mille per annum. This rate has accordingly been adopted as the "natural" rate of increase for Madras.

35. In Bombay the movement of population has been subject to violent fluctuations. After the bad famine of 1844-45 the male population increased up to 1872 at an average rate of 11·4 per mille per annum (1881 Census Report, Volume I, page 157), between 1872 and 1881 the population diminished, the average rate over the whole period 1844—1881 being 7·8 per mille. Between 1881 and 1891 the annual rate of increase was nearly 14 per mille, while during the past decade the population has diminished by about 2 per mille per annum, giving an average rate of increase of 6 per mille for the past 20 years. Combining this latter rate with the average of 7·8 per mille prior to 1881, we may assume a mean rate of 7 per mille as probably representing very approximately an average of the last 50 or 60 years.

36. In Bengal the movement of population has been much more uniform—in 1878—1880 there was no serious famine, although the birth-rate was somewhat reduced, as has again been the case in recent years. The mean rate of increase prior to 1881 was estimated at 8 per mille per annum, due allowance having been made for improved enumeration. In the decade 1881—1891 the average annual rate of increase was 7·3 per mille, and in the last decade 1891—1901 was 5·0 per mille, giving an average of a shade over 6 per mille for the last

20 years. Taking a mean between this rate and the rate prior to 1881, we get 7 per mille per annum as representing, probably fairly closely, the normal rate of increase, and this rate was accordingly adopted.

37. The North-West Provinces appear to have experienced with great regularity alternations of stagnation and progress. The average rate of increase for about 50 years prior to 1881 was estimated at $3\frac{1}{4}$ per mille per annum (Census Report, Volume I, page 155). The average rate of increase since 1881 has been 3.5 per mille, but if an allowance be made for emigration of about 1.2 per mille, this gives a "natural" rate of increase of 4.7 per mille. The normal rate adopted is 4 per mille per annum.

38. In the Punjab again the movement of the population has been fairly steady. The average rate of increase for the British territory prior to 1881 (1855—1881), after making allowance for improved enumeration and for emigration, was assumed to be not greater than 6 per mille per annum (1881 report, Volume I, page 157). Since 1881 it has exceeded this figure, averaging 9.9 per mille in the period 1881—1891 and 6.8 per mille for the following 10 years (making due allowance for changes in area), thus giving an average of 8.4 per mille for the last 20 years.

The birth-place returns do not indicate that any material correction should be made to this figure on account of emigration. On the whole, the period 1891—1901 may be considered as fairly normal, the birth-rate being well maintained, the previous decade 1881—1891, as was the case almost throughout India, being exceptionally favourable. If a rate of increase of 6 per mille is assumed for the period 1855—1881, we get an average rate for the past 46 years of 7.1 per mille per annum, approximating closely to the experience of the past 10 years. I have therefore assumed a normal rate of 7 per mille per annum, as in the case of Bengal and Bombay.

39. In Burma, as already stated, the Buddhist population alone was dealt with in order to eliminate any serious difficulties as to immigration. Here the recorded increase since 1891 amounts to 19.4 per cent., or about 17.9 per mille per annum, and in the previous decade the rate of increase was still higher. It appears to me quite certain that this recorded rate is much higher than the true figures, and that improved enumeration must be answerable for some considerable share of this large increase. The progression of the graduated age figures would indeed indicate that if the natural rate of increase in the population is 18 per mille per annum, then the mortality rates from about 10 to 25 must be nearly zero. Mr. Lewis, in his report on the Burma census (Volume I, pages 19—24), has discussed the observed increase of population from various points of view, and arrives at the conclusion that if certain districts are excluded where the recorded increase is quite abnormal, the average increase for Upper Burma for the past 10 years would be 11.2 per cent. equivalent to 10.7 per mille per annum. Part of the abnormal increase in the districts referred to may be due to emigration from the remaining districts, and, having regard to the fact that Burma has been free from any scarcity, and that the relatively large numbers of the population returned at the older ages indicates much lower rates of mortality than those prevailing in India generally, it will not be an extreme assumption that the "natural" rate of increase of the population is about 12 per mille per annum about equal to the rate in non-famine periods in Madras and Bombay.

The Female age Tables.

40. The graduation of the female age tables presents the same or greater difficulty than is the case for the male sex, as the statements of age are less trustworthy, and in many districts the enumeration of the female population is not very complete. Both in 1881 and 1891 it was found necessary on this ground to deal independently with the female age tables in Madras and Bengal only, the proportion of females enumerated in these provinces going to show that the enumeration was fairly satisfactory. In the remaining districts it was found necessary to assume that the same relation between numbers of females and males living at various ages would be found to hold as in Madras and Bengal.

41. The following table gives the number of females enumerated for each 10,000 males in the various provinces for the three censuses, 1881, 1891 and

1901. It will be seen that on the whole there has been a slight increase since 1881 in the relative number of females, with the exception of Bengal:—

Females enumerated for each 10,000 males in the undermentioned provinces.

Province.	1881 census.	1891 census.	1901 census.	Mean giving double weight to 1891 figures.
Bengal	10,084	10,062	9,995	10,051
Bombay	9,865	9,814	9,882	9,844
Madras	10,210	10,222	10,279	10,238 (a)
North-West Provinces	9,249	9,878	9,800	9,834 (b)
Punjab	8,483	8,589	8,563	8,518 (c)
Burma (Buddhists)	10,273	10,273

(a) Reduced to 10,000 when allowance is made for male emigration.

(b) Ditto 9,025 ditto ditto

(c) Ditto 8,411 when allowance is made for excess of female immigration.

42. The ratio of females to males would appear to be less in India than in western countries, and differs very considerably in the various provinces, being extremely low in the Punjab, where, however, no marked advance appears to have taken place in this respect since 1881. It does not appear practicable to determine how far this apparent defect in the female population is due to imperfect enumeration in certain provinces, but it is very probable that this is in part an explanation of the low figures in the Punjab, otherwise it must be assumed that the rate of mortality among the Punjab females is much higher relatively than in the remaining provinces.

43. The table given below deals with the subject in more detail, giving the ratio of females to males for certain special age groups, selected, so as to avoid disturbances arising from the heaped up figures at the quinquennial ages.

These figures are based upon the figures given in Table B and upon the corresponding figures in the 1891 census report, and assume a total population for each province of 100,000 males and 100,000 females. For purposes of comparison the numbers at birth, as derived from the past five years' registration returns (1896—1901), are also inserted, reduced to the same basis of a total population of 100,000 of each sex.

TABLE III.

Showing number of females to 1,000 males at the undermentioned ages in the provinces indicated for 1891 and 1901, etc.

Province	Age	Ratio of males to females	Ratio F to 1,000		Mean of ratios	Reduced to 1,000 at birth
			1891	1901		
Malabar	At Birth	0	962	955	959	1,000
	0 - 7½	21	1,016	1,014	1,015	1,058

Burma	37½-47½	62½	...	1,061	...	1,071
	Over 47½	72½	...	1,208

44. It will be seen generally that while there is a defect in the numbers of females returned at the younger ages, after middle life they are in excess of the males, as is usually found to be the case in other communities, but it is impossible to say how far the excess in numbers at the older ages may be taken to represent actual facts. The returns of Burma in this respect are especially interesting, as on the grounds already stated there is good reason to believe that the age statistics for Burma are more accurate than for the remaining provinces. It is not very probable that the relative mortality of males and females at various periods of life is greatly different in the various parts of India, and the same course might have been followed on the present occasion as in 1901, the relation of the mortality rates for the two sexes derived from the Madras and Bengal returns being applied to the remaining provinces. It was thought better, however, to make a separate set of ratios for each province based upon the figures in the above tables. A smooth curve having been drawn in each case representing the ratio of the number of females to 1,000 males at each age from birth onwards, preserving as far as possible the general features of the unadjusted ratios given above, while removing the larger irregularities, these adjusted ratios were applied to the numbers living at each age (L_x) in the male mortality tables, and the corresponding values of (L_x) for the female tables were thus deduced. It must be recognised that the extreme uncertainty of the age tables in the case of the females and their obvious anomalies make it impossible to draw from them any but the most general conclusions. In the case of the Punjab the female table has been omitted, as the figures would appear to be quite untrustworthy.

THE CENSUS AS TEST OF DEATH REGISTRATION.

45. It may be useful to add here a note upon the use of the census figures as a rough test of the relative completeness of the registration returns in the various provinces. From the known imperfection of these returns it results that all calculations as to increase of population based thereon are vitiated, and almost the only information derivable from these returns—information which, however, is no doubt of considerable importance—is the relative mortality for different years in the various provinces. Moreover, owing to the method in which the ages are grouped in decennial periods above age 20, the large number of deaths which we may be sure are returned at the individual ages 20, 30, 40, etc., are all included in the respective groups commencing with these ages, and as a consequence the registration returns cannot safely be employed even to determine the relative mortality for different periods of life.

46. If we consider the entire population in a given province as enumerated in 1891, and the population enumerated in 1901 for the same province at 10 years old and upwards, we shall see that, neglecting minor considerations, such as migration, and making due allowance for any inaccuracy in the age returns, the latter group represent the survivors of the former, and the difference between the two populations would be represented approximately (if we suppose the deaths uniformly spread over the period) by the deaths during the decennium aged 5 years and upwards. This assumption will not be very accurate owing to the rapid change in the death-rate during the first two or three years of life, and, considered alone, would have the effect of under-estimating the proportion of deaths registered to those actually occurring, but this tendency will probably be corrected by the larger probability that deaths of quite young children will escape registration, hence the figures as given may be taken as sufficiently near for practical purposes.

47. In the following table is set out the total population under registration (omitting the 1,000's) for the various provinces in 1891, and (in column 4) the survivors of such populations living at ages 10 years older in 1901, the differences as given in column 5 showing the estimated deaths for the 10 years, which may be taken practically to correspond to the deaths for the decade at age 5 and upwards. There is added in column 6 the registered deaths, age 5 years and upwards, for the same period, the populations of the various provinces having been reduced to agree with the populations under registration. A comparison of the figures in columns 5 and 6 for the various provinces as carried out in the remainder of the table, the headings of which will be found sufficiently explanatory, will show the extent to which death registration is probably defective in each of these provinces.

TABLE IV.

Provinces.	Average population under registration (as at 1891 census). (Males.)	Corresponding population. In 1891. (Males.)	Estimated no. in last column, aged 10 and upwards, being survivors of no. in column (2).	Deaths in 10 years out of no. in column (2), aged 5 years and upwards. In average 5 years and upwards).	Registered deaths, aged 5 years and upwards. (1891-1901).	Registered deaths at all ages (1891-1901).	Estimated deaths at all ages (1891-1901). $\frac{6}{5} \times (7)$.	Death-rate per 1,000 on mean population (1891-1901). $\frac{6}{5} \times (8)$.	Death-rate per 1,000 registered population (1891-1901). $\frac{6}{5} \times (9)$.	Estimated birth-rate per 1,000 (1891-1901). (Males). $\frac{6}{5} \times (10)$.	
Bengal	34,964	36,747	25,953	9,011	7,710	11,033	13,030	38.0	34.1	36.0	43.0

Only the birth-periods of the first few individuals in each period were used.

MONITORING OF AIR POLLUTION

— *and the number, and the cause, of the deaths of Insane and*

48. The population tables might also enable us to attempt some correction of the ages given in the returns of registered deaths, if we could safely make the assumption that the nature and extent of the errors in the statements of age for the purpose of death registration are similar to those of the errors in the census returns. The doubt attaching to this assumption would however, render any conclusions based upon it of very little value. Speaking very generally, it may be taken that the deaths returned at ages 60 and upwards represent, roughly, those over ages 57 and $57\frac{1}{2}$, those over 50 roughly represent the true relative numbers over $47\frac{1}{2}$, and so on, the extent of the error being much diminished as we reach the earlier ages.

49. It would appear hopeless for many years to come to expect anything like complete registration of births and deaths in India, and I would suggest that it would be well to concentrate efforts in this direction upon certain small but representative areas in various parts of India.

Owing to the thoroughness of registration in the Proclaimed Clans districts we are much better informed as to the rates of mortality prevailing during childhood than we could possibly be if we had to rely on the census returns and the ordinary registration of deaths. If a community is sufficiently large to give 30,000 or 40,000 persons constantly under observation, and registration carried on under such conditions as would ensure its practical completeness, very valuable results would be in a few years obtainable from such observations, especially if a sufficient number of such communities could be selected in different parts of India to make them in the aggregate fairly representative of India as a whole.

50. It is also worth while to consider whether a different age grouping might not be adopted in the death returns, the decennial groups being taken from 15 to 25, 25 to 35, and so on, or quinquennial groups being adopted throughout. Still better of course would be the return of the numbers for each age both in respect of population as enumerated at the census and in respect of registered deaths.

51. From the estimated defect in the number of registered deaths for the decennium in the principal provinces as given in Table IV, combined with the known rate of increase of the population during the past ten years, an estimate may be made of the birth-rate for the period. The result of this estimate for each province is set out in column (11) of Table IV.

Relative mortality of the periods 1881 to 1891 and 1891 to 1901.

52. A comparison of the numbers living in 1881 with the survivors ten years older in 1891, and similarly of the numbers living in 1891 with the survivors ten years older in 1901, gives us a ready means of determining approximately the relative mortality of the two decennia, and thus of comparing the death-rates during a period of scarcity and (in some districts) of plague, with the rates prevailing during a period of comparative plenty. This method of comparison will throw no light on the relative mortality during infancy, as the effect of increased mortality is overlaid by that of a diminished birth-rate. Thus the actual number of deaths in infancy during a period of famine may be but little in excess of those occurring during a period of plenty owing to the much smaller number of children born, although the death-rate per mille may be very considerably higher. This disturbing factor, however, mainly affects the first few years of life, and as the results of the method have reference only to the mortality for ages above 5, they may be taken as giving a rough approximation to the truth.

53. The following table is given to bring out results of this comparison as applied to the principal provinces, and will show how greatly different the rates of mortality are in India under adverse circumstances from those prevailing under more favourable conditions. In Bombay in particular, where to the effects of famine has been superadded the severe visitations of plague, the death-rate for the past quinquennium on the average has been more than 50 per cent. higher than that for the preceding ten years. When it is considered that this difference in the death-rate for ten years means about three million additional deaths in this period for the province of Bombay alone, it will be seen how serious is the inroad made by these periodical visitations upon the Indian population.

TABLE V.

Relative mortality rates (males) for the periods 1881—1891 and 1891—1901.

PROVINCE.	1881—1891.			1891—1901.		
	Assumed population, 1881.	Survivors thereto in 1891, aged 10 and upwards.	Mean death-rate per annum (2)—(3)	Assumed population, 1891.	Survivors thereto in 1901, aged 10 and upwards.	Mean death-rate per annum (5) + (6)
			$\frac{5}{5} \times \frac{(2) + (3)}{(4)}$			$\frac{5}{5} \times \frac{(5) + (6)}{(7)}$
(1)	(2)	(3)	(4)	(5)	(6)	(7)
Bengal . . .	100,000	74,841	.0288	100,000	74,227	.0296
Bombay . . .	100,000	80,870	.0212	100,000	71,499	.0332
Madras . . .	100,000	80,623	.0205 (a)	100,000	75,315	.0272 (a)
North-West Provinces .	100,000	77,034	.0247 (b)	100,000	74,767	.0277 (b)
Punjab . . .	100,000	77,526	.0253	100,000	77,727	.0251

* Corresponding approximately to mean death-rate of males aged 5 and upwards during the ten years.

(a) Reduced by .0010 to allow for effect of emigration.

(b) Reduced by .0012 to allow for effect of emigration.

Final Tables.

54. The tables of mortality and expectations of life appended to the report marked E to R have been based upon the graduated population tables as given in Table D, upon the assumption that these tables may be taken to represent the normal age distribution for the various provinces, and that the average rate of increase in these provinces is as given above. The resulting rates of mortality and expectations of life are somewhat different to those that would be obtained by a comparison of the adjusted numbers living in 1881 and 1901, representing the average mortality for the 20 years, but it is probable that even a period of 20 years is hardly sufficiently long to give a fair average in India, where such enormous differences in rates of mortality are revealed in successive decades. The tables now given should therefore approximate in their character to those given in the memorandum upon the 1881 census, as, like the latter, they are intended to show the normal rate of mortality after due allowance has been made for the effect of periodically recurring famines.

55. When the uncertainty of the data is taken into account, the present results may be taken to show that, setting aside the large fluctuations due to periods of scarcity and of plague, the average birth and death-rates in India do not give any indication of permanent change. It is of course a mere truism that a high birth-rate involves either a correspondingly high death-rate, or, in the alternative, so rapid an increase in the population as to threaten to encroach upon the limits of subsistence under present conditions. As emigration on an extensive scale is out of the question, the alternatives for the future are either a reduction in the birth-rate as a result of the spread of education and a gradual change of social customs, or such a change in the conditions of life as will permit of a steady increase in the means of subsistence, or, finally, a continuance in future of such periods of famine, with their accompanying destruction of population, as have marked the past history of India.
